2- BREAKER BLOCK

- A breaker block is essentially a failed order block that signals a shift in market momentum. It forms after a strong price movement when the market fails to sustain its direction and reverses.
- Once this reversal occurs, the failed order block assumes the opposite role—turning a broken bearish order block into a bullish breaker when price closes above its high, or a broken bullish order block into a bearish breaker when price closes below its low.

entri

Bearish breaker block

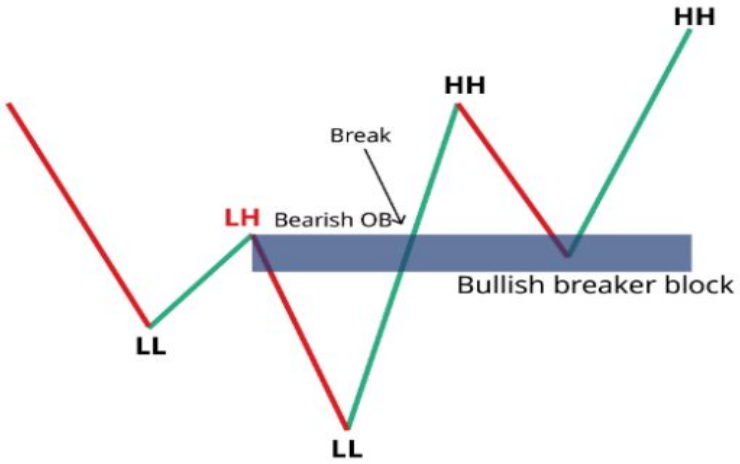

- Steps to Identify a Bearish Breaker Block:

1. **Spot a bullish order block:** Identify a zone where price previously consolidated before a strong bullish move.
2. **Watch for breakdown:** Wait for price to move below this area with momentum, ideally after a liquidity grab or stop hunt
3. **Monitor the retest:** Price may come back up to retest the same zone, which now acts as supply zone.

Bullish breaker block

entri

- Steps to Identify a Bullish Breaker Block:

1. **Locate a bearish order block:** Look for a consolidation zone or bearish candle before a strong move downward.
2. **Wait for invalidation:** Observe a clean price action breakout above this level, often confirmed by a candle close beyond the block.
3. **Look for a retest:** Price typically returns to the breaker block zone, which now acts as a demand zone.
